Colour Mock-Ups

	The blue background give a nice contrast from other contents, make the website look more professional, and give the users a calm vibe when using the website. But my client would like the color to be either lighter blue or brighter blue. Overall, this going to be a good contender.
	Red is not warm, but hot color. It's hard to not notice a red design in a website. So red is often used for logos, buttons or a small section of the page. In this case, the red color is alright as most of the background is located behind the body text section. But too much red color might annoy users and turn them away. So this choice is under consideration as the contents of each page might change, which might increases or decreases the visible background.

	There is a good contrast established in his mockup, but it hard for my client to see the text in the relatively dark red background for the body text. Also the main background is too pink, which might not be gender neutral as male don't typically like the color when they visit the website.
	The page contents really stand out in this background, as well as the brown navigation bar. Even though brown isn't following the website color schemes, but in biology, student will learned about plants and life. So brown color can associate with dirt and other material.
	This font is just like the one that I talk about earlier, with an exception of blue navigation bar. The blue and pink does improve the look of the page, but my client still don't like the pink color as it's only associate with one gender only and will bother the other.
	This site, considered by my client, will only work well if this was aiming for women only. This is not suitable for a biology website and will not me develop further.

My client has decided to choose this certain color scheme as the final result, even though more changes will be implemented in the future.

Welcome to 200 Biology
How can there be seedless grapes and bananas, and how do they reproduce? Where did we come from? Why is carbon monoxide extremely poisonous? Why can't you tickle yourself? What causes the smell after rain? How do vitamins work? What's all this fuss about stem cells? What makes us yawn? Why are frogs growing extra legs out of their legs? Which came first, the chicken or the egg?
Biology is the study of living things and their vital processes. Because biology covers such a large area, it has been traditional to separate the study of plants (botany) from that of animals (zoology), and the study of structure of organisms (morphology) from that of function (physiology). Despite their apparent differences, all the subdivisions are interrelated by basic principles, so current practice tends to investigate those biological phenomena that all living things have in common. The advancement of knowledge and technology has resulted in further categorizations that include, but are far from restricted to: cell biology, population biology, ecology, genetics, biochemistry, molecular biology, microbiology, agriculture and physical anthropology.
